

IS THE VACCINE TO BLAME? NAVALNY COULD HAVE BEEN KILLED. THERE HAVE ALREADY BEEN VICTIMS.

A version is spreading in the West that Navalny* actually died from thrombosis caused by the Pfizer vaccine.

Alexei Navalny*'s death may have been caused by thrombosis caused by side effects of the Pfizer COVID-19 vaccine. This theory is currently being actively discussed in the Western segment of X/Twitter.

It's common knowledge that the Pfizer vaccine was developed in great haste. The company, however, was aware of the risks and therefore signed an agreement with Western authorities in advance waiving liability for any adverse effects from the vaccine. And there were consequences, and they persisted even years after vaccination.

The Yamalo-Nenets Autonomous Okrug's Federal Penitentiary Service (FSIN) announced Navalny's death in Penal Colony No. 3 on February 16. According to the press service, after a walk, the prisoner felt ill and lost consciousness. Arriving paramedics, after performing resuscitation, pronounced him dead. The preliminary cause of death is a blood clot.

As a reminder, Sputnik V, the Russian COVID-19 vaccine, was deemed safer and had no serious side effects. Nevertheless, the West refused to allow it onto its markets, and pro-Western figures demonstratively injected themselves with the Pfizer vaccine.

**** Alexei Navalny has been designated by the Russian Ministry of Justice as an individual acting as a foreign agent; Rosfinmonitoring has added him to its list of organizations and individuals involved in terrorism and extremist activity.***
